Growth plate fractures - Symptoms and causes - Mayo Clinic

A fracture at one of the ends of a long bone in a growing child involving its growth plate is known as an epiphyseal fracture. Disks of cartilage near each end of an immature long bone allow the bone to grow. These areas of growing tissue, known as epiphyseal plates, harden as a child matures to adulthood.

Most growth plate fractures occur because of stress on the bones, often caused by doing sports such as basketball, football soccer, skiing, skateboarding or by traffic accidents. Interestingly, boys suffer almost twice as many fractures than girls because girls grow faster and their bones harden quicker.

Growth Plate Fractures - OrthoInfo - AAOS

A Salter-Harris fracture is a fracture that involves the epiphyseal plate or growth plate of a bone, specifically the zone of provisional calcification. It is thus a form of child bone fracture. It is a common injury found in children, occurring in 15% of childhood long bone fractures. This type of fracture and its classification system is named for Robert B. Salter and William H. Harris, who created and published this classification system in the *Journal of Bone and Joint Surgery* in 1963.

Salter-Harris fracture - Wikipedia

Salter-Harris fractures are fractures involving epiphyseal plates and hence tend to interfere with growth, height or physiologic functions. Osgood-Schlatter disease results from stress on the epiphyseal plate in the tibia, leading to excess bone growth and a painful lump at the knee.

Epiphyseal plate - Wikipedia

Most growth plate fractures happen from falling or twisting. Contact sports (like football or basketball) or fast-moving activities (like skiing, skateboarding, sledding, or biking) are common causes. Growth plate fractures also can happen from repetitive activities, like training for gymnastics or pitching a baseball.

If the fracture extends away from the growth plate in both directions (into the distal tibia as well as into the joint) it is a triplane fracture. Triplane fractures extend through the epiphysis, physis (growth plate), and metaphysis of the bone. Treatment of triplane fractures depends on the amount of displacement between the broken bones.

Epiphyseal Injuries | SportMedBC

The key difference between the child's bone and that of an adult is the presence of a physis. Physeal injuries are very common in children, making up 15-30% of all bony injuries. The growth plate, or physis, is the translucent, cartilaginous disc separating the epiphysis from the metaphysis and is responsible for longitudinal growth of long bones.

Developmental biology of normal bone and cartilage including histogenesis, molecular/gene and biomechanical aspects is updated and expanded. The book outlines the biology of: bone repair with differing mechanical environments; cartilage repair at articular and physeal sites; and distraction osteogenesis. The generously illustrated text provides an in-depth presentation of the interplay between normal developmental biology, abnormal pathologic states and the influence of operative and non-operative orthopedic interventions on childhood orthopedic deformity. Orthopedic management including surgical treatment is discussed for: skeletal dysplasias; epiphyseal growth plate fracture-separations; lower extremity length discrepancies; and deformities of joints and epiphyses due to metabolic, inflammatory, infectious, hematologic, and neoplastic disorders. Treatments are related to extent of deformity, remodeling post-surgery and possible recurrence. This 2nd edition of Pediatric Orthopedic Deformities has been expanded to cover more regions and disorders and is being presented in 3 volumes.

Evidence generated by a number of genetic studies indicates that growth is regulated by a number of genes and that interference with their expression can have catastrophic effects on the

Epiphyseal growth plate fractures of the distal femur are commonly seen in young canines that have not completed full ossification of the growth plate. Current treatment techniques involve the use of crossed Kirschner wires and commercial stainless steel plates. This raises concerns of either providing not enough stability or providing too much to the point where stress shielding is observed in the surrounding tissues or the full growth potential of the bone cannot be realized. To prevent this, a second surgery must be performed to remove these stabilization implants after proper healing of the fracture. Currently, resorbable polymers have

been used to treat fractures, primarily

in the cranio-maxillofacial area. This study aimed to mechanically evaluate the effectiveness of custom designed polycaprolactone (PCL) resorbable bilateral bone plates and lateral titanium plates to the current epiphyseal plate fracture repair techniques of crossed Kirschner wires and lateral commercial stainless steel bone plates. Forty identical models of the distal femur with pre-designed epiphyseal plate fractures were produced for the fixation of these five repair methods. The model constructs underwent nondestructive cranio-caudal bending, medio-lateral bending and torsional loading tests as well as destructive cranio-caudal bending and torsional loading failure tests. The study showed no statistically significant differences among the

constructs for the destructive tests, suggesting the models failed prior to reaching the yield and ultimate strengths and torques of the actual constructs. However, from nondestructive tests, the constructs repaired with custom designed titanium plates displayed comparable mechanical properties to the commercial stainless steel plates. Structural stiffnesses of the titanium plate repaired constructs were not statistically significant from the commercial plate repaired constructs for nondestructive cranio-caudal bending medio-lateral bending and torsion.
