Crystallization is a technique which chemists use to purify solid compounds. It is one of the fundamental procedures each chemist must master to become proficient in the laboratory.

Crystallization is based on the principles of solubility: compounds (solutes) tend to be more soluble in hot liquids (solvents) than they are in cold liquids.

## **Crystallization - Organic Chemistry**

Crystallization of organic compounds (such as drug substances, other active ingredients, and key intermediates) is a means used for isolation of specialty bulk products with desired quality attributes, in pharmaceutical, food, fine chemical and cosmetics industries.

In chemistry, recrystallization is a technique used to purify chemicals. By dissolving both impurities and a compound in an appropriate solvent, either the desired compound or impurities can be removed from the solution, leaving the other behind. It is named for the crystals often formed when the compound precipitates out.

## **Recrystallization (chemistry) - Wikipedia**

Recrystallization, also known as fractional crystallization, is a procedure for purifying an impure compound in a solvent. The method of purification is based on the principle that the solubility of most solids increases with increased temperature.

## **Recrystallization - Chemistry LibreTexts**

Crystallization is used in the chemistry laboratory as a purification technique for solids. An impure solid is completely dissolved in a minimal amount of hot, boiling solvent, and the hot solution is allowed to slowly cool.

### **3: Crystallization - Chemistry LibreTexts**

Recrystallization is a technique used to purify solid compounds. 1 Solids tend to be more soluble in hot liquids than in cold liquids. During recrystallization, an impure solid compound is dissolved in a hot liquid until the solution is saturated, and then the liquid is allowed to cool. 2 The compound should then form relatively pure crystals.

The most commonly used recrystallization solvents are presented in the following table. Organic compounds with one polar functional group and a low number of carbon atoms such as methanol, ethanol, and n-propanol are highly soluble (miscible) in water. These alcohols form hydrogen bond with water due to the polar -OH functional group.
